Hub location problems, classification and methods

Prof. Dr. Jack Brimberg

December 20, 2016

This talk presents a brief overview of hub location problems. The classical models assume that the triangle inequality holds everywhere on the network, although this is not always the case in practice. We derive two new model formulations that relax this assumption. Flows between origin-destination pairs may now pass through more than two intermediate hub nodes. A variable neighborhood search is also proposed to solve the new problem and preliminary computational results given.
